TITLE: Wireless file transmission

----- KWIC -----

Detail Description Paragraph - DETX (282):

[0347] In order to minimize memory storage space, local software for the wireless interface device 100 is stored in a compressed format, for example, in a read only memory device (ROM), such as the flash memory devices 742-748 (FIG.

25), then decompressed, written and executed from the DRAM memory devices 111A

(FIG. 18). As will be discussed in more detail below, both .EXE files and .COM

files, as well as various other types of files are compressed and decompressed.

An .EXE file is any executable file with an extension .EXE, i.e., FIND.EXE,

MSD.EXE. A .COM file is any executable file with an extension .COM, i.e.,

EDIT.COM, SYS.COM. Such files, as known by those of ordinary skill in the art,

include a header portion as well as a data, or code portion, where either data

or a software program is stored. An exemplary header for an .EXE file is

illustrated in Table 8 below.

Detail Description Paragraph - DETX (289):

[0354] The overall flow chart for the compression/decompression process is

shown in FIG. 75. Initially, files are compressed and transmitted to the

wireless interface device 100. In particular, the compressed files are written

directly to the flash memory devices 742. In order to execute the file, the

compressed file from the flash memory device 742 is written to a temporary file

within the DRAM memory devices 111a (FIG. 18) in the memory space 10000 to

1FFFFFF. In such an application, the flash memory devices 742 act as input

files, while the temporary file in the DRAM memory devices 111a serves as an

output file. Alternatively, new files to be written to the flash memory

devices 742 are initially uncompressed and stored in an external input file 1896, external from said wireless interface device 100. The input file 1896 is then compressed and stored in an output file 1898. The compressed output file 1898 is then transferred to the flash memory devices 742 within the wireless interface device 100 over a radio link. Thus, in step 1900, depending upon whether compressed data is being written to the flash memory devices 742, or whether the compressed data within the flash memory device is being executed, input and/or output files 1896, 1898 are opened in step 1900 as generally discussed above. If the file is to be transferred to the flash memory devices 742 in the wireless interface device, the file is compressed and written to an output file 1898 and transferred to the flash memory devices 742, as indicated by steps 1902 and 1904. For files that are currently stored in the flash memory devices 742 in a compressed format, these files are decompressed and written to an output file 1898 for execution as indicated in steps 1902 and 1904.

Detail Description Paragraph - DETX (294):

[0359] After the customized file header 1882 is formed and written to the output file 1898, the data or code portion 1888 (FIG. 79) for both .EXE and .COM files, is read, compressed and written to the output file 1898 in steps 1938-1944. In order to identify the beginning of the data or code portion 1888, the signature field 1890 may include a data image index which indicates the memory location of the data or code portion 1888 in the input file 1896. Since the customized header 1882 may be at least partially compressed, the address location in the output file 1898 of the beginning of the data or code portion 1888 is modified in the signature field 1890 in the output file 1898 in step 1938. Subsequently, space is reserved in the output file 1898 for the data or code portion 1888 of the file in step 1940. The data or code portion 1888 is then read from the input file and compressed according to known

compression techniques, for example, as discussed above, and written to the output file 1898 in step 1942. After the compressed data is written to the output file 1898, the size of the compressed data or code portion 1888 is written to the output file 1898 in step 1944.

Detail Description Paragraph - DETX (295):

[0360] The flow chart for decompressing stored compressed files in the flash memory devices 742-748 is illustrated in FIG. 77. Initially, any file to be executed is in a compressed format as discussed above. Initially, as indicated by step 1946, the signature field 1890 (FIG. 78) is read from the input file 1896. After the signature field 1890 is read from the input file 1896, the customized file header 1882 is read in step 1948. As mentioned above, the signature field 1890 identifies whether the particular file is an .EXE file or a .COM file. Thus, the system ascertains in step 1950 whether the file is an .EXE file or a .COM file. As indicated above, the signature field 1890 (FIG. 79) may include data regarding the file as to whether it is an .EXE file or a .COM file, as well as the software version of the compression software in order to speed up the decompression process. Before the file can be decompressed, the size of the compressed data or code portion 1888 (FIG. 79) must be ascertained. As indicated above, for .EXE files, the size of the header may be ascertained directly from the customized file header 1882 (FIG. 79). Since the header for a .COM file is compressed in the same manner as the code portion 1888 for the .COM file, the header portion 1882 is treated the same as the code portion 1888. Thus, the entire .COM file, header portion 1882 and code portion 1888 are written directly into the output file 1898 (FIG. 78) in step 1952. In the case of .EXE files, the customized file header 1882 is written to the output file 1898. The system then reads the size of the block in step 1954. In the case of a .COM file, the size of the compressed data or code block may be read directly from the flash memory device 742. In the case of an .EXE file, the file header is partially compressed, as indicated above, in

data
blocks. Thus, in steps 1954-1958, the system reads decompressed blocks
of data
from the input file 1896 and writes the decompressed data to the output
file
1898. Both the headers portions 1882, as well as the data or code
portions
1888 are decompressed one data block at a time by the loop consisting
of the
steps 1954-1958. Once all of the data has been decompressed, including
the
header, the decompressed file may be executed directly from the output
file
1898, which may be a part of the DRAM 111A.

Detail Description Paragraph - DETX (14):

[0054] CPU 15 controls operation of the DSC at each constituent sectors in accordance with programs stored in, for example, a flash memory 16.

DRAM 17

temporarily stores the image data compressed in the JPEG sequence at the

compression/decompression circuit 14 delivered via a main bus. Part of the

DRAM 17 area is allocated as the work area for the CPU 15.

Detail Description Paragraph - DETX (19):

[0059] Then, the CPU 15 adds header information containing the JPEG compressed thumbnail image, date/time of the picture taken, particulars of the

camera used and other picture shooting conditions, etc. to the JPEG compressed

file stored in the DRAM 1. An Exif format file is thus formed. Next, the CPU

15 makes an access to the memory card 25 via memory card controller 26, refers

to the FAT (File Allocation Table) disposed in a certain predetermined area of

memory card 25, and searches a directory 100ABCDE (30) provided in a lower

branch of the directory 7 for storing still image files.

ABSTRACT:

The identification information of a base station used to identify this station is stored in relation to position information. If received identification information is stored when an image is photographed, position information corresponding to the stored identification information is added to the image data.

Detailed Description Text - DETX (129):

SOI (Start Of Image) is in the first position of the file. In APPO (Application reservation start marker), a declaration (JFIF marker) indicating that the file has the JFIF format is arranged first and followed by a header indicating the contents.

Detailed Description Text - DETX (187):

In step S2203, the CPU 215 reads out the compressed image data, written in step S2021 of FIG. 20A (photographing operation), from the flash ROM 213. In step S2204, the CPU 215 executes image decompression processing, i.e., processing for converting the compressed data based on the JPEG standard into original data (YCrCb). In step S2205, the CPU 215 writes the decompressed original data into the memory (DRAM 220).

Detailed Description Text - DETX (217):

In this embodiment, CS-ID information is acquired at an interval of one minute from the start to the end of photography. The date/time information and the CS-ID information are recorded in a user extension area of each picture frame header of an MPEG2 image.

ABSTRACT:

A system which enables a plurality of wireless interface devices to be connected by way of a radio link to a server in either a wired or wireless LAN. On power-up for the wireless interface device, the wireless interface device upon initiation broadcasts for available servers available for connection. The system automatically determines the server with the least amount of load and displays that server on a dialog box on the display of the wireless interface device. The user is then able to select that server from the dialog box.

Detailed Description Text - DETX (280):

In order to minimize memory storage space, local software for the wireless interface device 100 is stored in a compressed format, for example, in a read only memory device (ROM), such as the flash memory devices 742-748 (FIG. 25),

then decompressed, written and executed from the DRAM memory devices 111A (FIG.

18). As will be discussed in more detail below, both .EXE files and .COM

files, as well as various other types of files are compressed and decompressed.

An .EXE file is any executable file with an extension .EXE, i.e., FIND.EXE,

MSD.EXE. A .COM file is any executable file with an extension .COM, i.e.,

EDIT.COM, SYS.COM. Such files, as known by those of ordinary skill in the art,

include a header portion as well as a data, or code portion, where either data

or a software program is stored. An exemplary header for an .EXE file is

illustrated in Table 8 below.

Detailed Description Text - DETX (287):

The overall flow chart for the compression/decompression process is shown in

FIG. 75. Initially, files are compressed and transmitted to the wireless

interface device 100. In particular, the compressed files are written directly

to the flash memory devices 742. In order to execute the file, the compressed

file from the flash memory device 742 is written to a temporary file within the

DRAM memory devices 111a (FIG. 18) in the memory space 10000 to 1FFFFF.

In such an application, the flash memory devices 742 act as input files, while the temporary file in the DRAM memory devices 111a serves as an output file.

Alternatively, new files to be written to the flash memory devices 742 are

initially uncompressed and stored in an external input file 1896, external from

said wireless interface device 100. The input file 1896 is then compressed and

stored in an output file 1898. The compressed output file 1898 is then transferred to the flash memory devices 742 within the wireless

interface device 100 over a radio link. Thus, in step 1900, depending upon whether

compressed data is being written to the flash memory devices 742, or whether

the compressed data within the flash memory device is being executed, input

and/or output files 1896, 1898 are opened in step 1900 as generally discussed

above. If the file is to be transferred to the flash memory devices 742 in the

wireless interface device, the file is compressed and written to an output file 1898 and transferred to the flash memory devices 742, as indicated by steps 1902 and 1904. For files that are currently stored in the flash memory devices 742 in a compressed format, these files are decompressed and written to an output file 1898 for execution as indicated in steps 1902 and 1904.

Detailed Description Text - DETX (292):

After the customized file header 1882 is formed and written to the output file 1898, the data or code portion 1888 (FIG. 79) for both .EXE and .COM files, is read, compressed and written to the output file 1898 in steps 1938-1944. In order to identify the beginning of the data or code portion 1888, the signature field 1890 may include a data image index which indicates the memory location of the data or code portion 1888 in the input file 1896. Since the customized header 1882 may be at least partially compressed, the address location in the output file 1898 of the beginning of the data or code portion 1888 is modified in the signature field 1890 in the output file 1898 in step 1938. Subsequently, space is reserved in the output file 1898 for the data or code portion 1888 of the file in step 1940. The data or code portion 1888 is then read from the input file and compressed according to known compression techniques, for example, as discussed above, and written to the output file 1898 in step 1942. After the compressed data is written to the output file 1898, the size of the compressed data or code portion 1888 is written to the output file 1898 in step 1944.

Detailed Description Text - DETX (293):

The flow chart for decompressing stored compressed files in the flash memory devices 742-748 is illustrated in FIG. 77. Initially, any file to be executed is in a compressed format as discussed above. Initially, as indicated by step 1946, the signature field 1890 (FIG. 78) is read from the input file 1896. After the signature field 1890 is read from the input file 1896, the customized file header 1882 is read in step 1948. As mentioned above, the signature field

1890 identifies whether the particular file is an .EXE file or a .COM file.

Thus, the system ascertains in step 1950 whether the file is an .EXE file or a .COM file. As indicated above, the signature field 1890 (FIG. 79) may include data regarding the file as to whether it is an .EXE file or a .COM file, as well as the software version of the compression software in order to speed up the decompression process. Before the file can be decompressed, the size of the compressed data or code portion 1888 (FIG. 79) must be ascertained.

As indicated above, for .EXE files, the size of the header may be ascertained directly from the customized file header 1882 (FIG. 79). Since the header for a .COM file is compressed in the same manner as the code portion 1888 for the .COM file, the header portion 1882 is treated the same as the code portion 1888. Thus, the entire .COM file, header portion 1882 and code portion 1888 are written directly into the output file 1898 (FIG. 78) in step 1952.

In the case of .EXE files, the customized file header 1882 is written to the output file 1898. The system then reads the size of the block in step 1954. In the case of a .COM file, the size of the compressed data or code block may be read directly from the flash memory device 742. In the case of an .EXE file, the file header is partially compressed, as indicated above, in data blocks. Thus, in steps 1954-1958, the system reads decompressed blocks of data from the input file 1896 and writes the decompressed data to the output file 1898. Both the headers portions 1882, as well as the data or code portions 1888 are decompressed one data block at a time by the loop consisting of the steps 1954-1958. Once all of the data has been decompressed, including the header, the decompressed file may be executed directly from the output file 1898, which may be a part of the DRAM 111A.

ABSTRACT:

A system for compressing program files at a remote host computer and transmitting the compressed program files to one or more wireless interface devices using a wireless link. The received compressed files are stored in an electronically programmable storage device on the wireless interface device.

The remote host includes a CPU, a storage device for running and storing one or more programs and a wireless link for communicating with the wireless interface device. The wireless interface device is able to control and access the one or more programs on the remote host using the wireless link.

----- KWIC -----

Detailed Description Text - DETX (289):

In order to minimize memory storage space, local software for the wireless

interface device 100 is stored in a compressed format, for example, in a read only memory device (ROM), such as the flash memory devices 742-748 (FIG. 25), then decompressed, written and executed from the DRAM memory devices 111A (FIG. 18). As will be discussed in more detail below, both .EXE files and .COM files, as well as various other types of files are compressed and decompressed. An .EXE file is any executable file with an extension .EXE, i.e., FIND.EXE, MSD.EXE. A .COM file is any executable file with an extension .COM, i.e., EDIT.COM, SYS.COM. Such files, as known by those of ordinary skill in the art, include a header portion as well as a data, or code portion, where either data or a software program is stored. An exemplary header for an .EXE file is illustrated in Table 8 below.

Detailed Description Text - DETX (296):

The overall flow chart for the compression/decompression process is shown in FIG. 75. Initially, files are compressed and transmitted to the wireless interface device 100. In particular, the compressed files are written directly to the flash memory devices 742. In order to execute the file, the compressed file from the flash memory device 742 is written to a temporary file within the DRAM memory devices 111a (FIG. 18) in the memory space 10000 to 1FFFFF. In such an application, the flash memory devices 742 act as input files, while the temporary file in the DRAM memory devices 111a serves as an output file. Alternatively, new files to be written to the flash memory devices 742 are initially uncompressed and stored in an external input file 1896, external from said wireless interface device 100. The input file 1896 is then compressed and stored in an output file 1898. The compressed output file 1898 is then transferred to the flash memory devices 742 within the wireless interface device 100 over a radio link. Thus, in step 1900, depending upon whether compressed data is being written to the flash memory devices 742, or whether the compressed data within the flash memory device is being executed, input

and/or output files 1896, 1898 are opened in step 1900 as generally discussed above. If the file is to be transferred to the flash memory devices 742 in the wireless interface device, the file is compressed and written to an output file 1898 and transferred to the flash memory devices 742, as indicated by steps 1902 and 1904. For files that are currently stored in the flash memory devices 742 in a compressed format, these files are decompressed and written to an output file 1898 for execution as indicated in steps 1902 and 1904.

Detailed Description Text - DETX (302):

After the customized file header 1882 is formed and written to the output file 1898, the data or code portion 1888 (FIG. 79) for both .EXE and .COM files, is read, compressed and written to the output file 1898 in steps 1938-1944. In order to identify the beginning of the data or code portion 1888, the signature field 1890 may include a data image index which indicates the memory location of the data or code portion 1888 in the input file 1896. Since the customized header 1882 may be at least partially compressed, the address location in the output file 1898 of the beginning of the data or code portion 1888 is modified in the signature field 1890 in the output file 1898 in step 1938. Subsequently, space is reserved in the output file 1898 for the data or code portion 1888 of the file in step 1940. The data or code portion 1888 is then read from the input file and compressed according to known compression techniques, for example, as discussed above, and written to the output file 1898 in step 1942. After the compressed data is written to the output file 1898, the size of the compressed data or code portion 1888 is written to the output file 1898 in step 1944.

Detailed Description Text - DETX (303):

The flow chart for decompressing stored compressed files in the flash memory devices 742-748 is illustrated in FIG. 77. Initially, any file to be executed is in a compressed format as discussed above. Initially, as indicated by step 1946, the signature field 1890 (FIG. 78) is read from the input file 1896.

After the signature field 1890 is read from the input file 1896, the customized file header 1882 is read in step 1948. As mentioned above, the signature field 1890 identifies whether the particular file is an .EXE file or a .COM file.

Thus, the system ascertains in step 1950 whether the file is an .EXE file or a .COM file. As indicated above, the signature field 1890 (FIG. 79) may include data regarding the file as to whether it is an .EXE file or a .COM file, as well as the software version of the compression software in order to speed up the decompression process. Before the file can be decompressed, the size of the compressed data or code portion 1888 (FIG. 79) must be ascertained.

As indicated above, for .EXE files, the size of the header may be ascertained directly from the customized file header 1882 (FIG. 79). Since the header for a .COM file is compressed in the same manner as the code portion 1888 for the .COM file, the header portion 1882 is treated the same as the code portion 1888. Thus, the entire .COM file, header portion 1882 and code portion 1888 are written directly into the output file 1898 (FIG. 78) in step 1952.

In the case of .EXE files, the customized file header 1882 is written to the output file 1898. The system then reads the size of the block in step 1954. In the case of a .COM file, the size of the compressed data or code block may be read directly from the flash memory device 742. In the case of an .EXE file, the file header is partially compressed, as indicated above, in data blocks. Thus, in steps 1954-1958, the system reads decompressed blocks of data from the input file 1896 and writes the decompressed data to the output file 1898. Both the headers portions 1882, as well as the data or code portions 1888 are decompressed one data block at a time by the loop consisting of the steps 1954-1958. Once all of the data has been decompressed, including the header, the decompressed file may be executed directly from the output file 1898, which may be a part of the DRAM 111A.
